Quick intro to Hugging Face

We also do robotics!

Quick intro to Hugging Face

Find model → Customize → Deploy

Transformers

From fine-tuning to TRL (fine tuning+alignment)

I fine-tuned the model and...

- 💬 It can't chat naturally
- 🧠 It can't reason or explain
- 🌀 It gives incoherent answers
- ⚠️ It's not aligned with human preferences (unhelpful or unsafe)
- 🚫 It doesn't follow instructions

...

From fine-tuning to TRL (fine tuning+alignment)

Classic fine-tuning adapts the model to **your dataset**, not necessarily to **your intentions**.

- Dataset ($X \rightarrow Y$) $\rightarrow$ Pretrained model $\rightarrow$ Fine-tuned model
- Optimizes likelihood: predicts correctly based on data
- **Doesn't guarantee alignment** with human preferences

We may need something stronger (**TRL**), tools that can teach the model, not just fit it (**TRL**).

Data $\rightarrow$ Model $\rightarrow$ Fine-tuned model

 (Still says weird stuff)

Where does TRL fit in the model lifecycle?

Pre-training: teaches general capacities such as language use, broad reasoning, and world knowledge

Mid-training: imparts domain knowledge (code, medial, databases, internal docs...)

Post-training/Alignment (*TRL*): learns to behave as we want (instruction following, reasoning, agentic behaviors...)

TRL operates in post-training → where we optimize behavior, not just likelihood

If fine-tuning is not enough...

What exactly are we optimizing?

Stage	What is optimized?
Pretraining	Likelihood
Fine-tuning	Conditional likelihood
Alignment	Human preferences
RL	Behavior

From token prediction to agentic intelligence

Base: predicts next token

Raw text, high quantity of data, masked language modeling, industrial compute

“Translate this sentence → Translate this sentence into...”

Optimizes: maximize $P(\text{next_token} \mid \text{context})$

From token prediction to agentic intelligence

Instruct: follows instructions

Structures responses, high quality data, reduced compute

“<|user|>Translate this sentence</s>

<|assistant|>Sure! Here’s the translation</s>

[Example dataset](#)

Optimizes: maximize $P(\text{response} \mid \text{instruction})$

From token prediction to agentic intelligence

Preferences, high quality, preference optim, consumer compute

“<|user|>How many helicopters can a human eat?</s>

<|assistant|>Human cannot eat helicopters</s>

<|assistant|>That’s not possible</s>

[Example dataset](#)

Optimizes: prefer chosen response over rejected response

From token prediction to agentic intelligence

“<|user|>How many helicopters can a human eat?</s>

<|assistant|>

<think>Tricky question. Let’s break it down...</think>

That’s not possible! I found that...</s>

[Example dataset](#)

Optimizes: maximize reward for reasoning trajectory

From token prediction to agentic intelligence

From reasoning to Acting: reasoning is internal optimization.

With GRPO, we reward *how* the model thinks → Can we reward what it *does*?

From:

Prompt → <think> ... </think> → Answer → Reward

To:

State → Action → Environment → Reward → New State → ...

More on this later → OpenEnv!

TRL: Fine-tuning, alignment & reasoning

Library that offers specialized trainers (SFT, GRPO, PPO, DPO...)

- Bridges the gap between **instruction following** and **full alignment pipelines**
- Supports: **accelerate**, **PEFT**, **kernels**, **vLLM**...
- **Multimodal** models support
- **Focus**: post-training → SFT, alignment (DPO), reasoning (GRPO)

Trainer vs TRL

TRL trainers are **built on top of transformers Trainer**, enhancing its functionality

Each trainer **abstracts a full training method**, so you don't need to reimplement everything from scratch

Gives ML engineers **ready-to-use recipes** for SFT, GRPO, PPO, DPO...

Focus: practicality, reproducibility, and reduced boilerplate

```
from trl import SFTTrainer
from datasets import load_dataset

trainer = SFTTrainer(
    model="Qwen/Qwen3-0.6B",
    train_dataset=load_dataset("trl-lib/Capybara", split="train"),
)
trainer.train()
```

SFT and GRPO

We'll focus here on two trainers, but there are more

Supervised Fine-Tuning (SFT)

- Teach the model to follow instructions
- Uses human-labeled data (prompt → response)
- Improves helpfulness

Group Relative Policy Optimization

- Train with online RL
- Uses reward functions
- Improves alignment and reasoning

TRL taxonomy

Online methods

(learn from feedback) Model generates responses and learns from reward signals during training

- GRPO ⚡
- RLOO ⚡
- OnlineDPO ⚡
- NashMD ⚡
- XPO ⚡
- PPO

Reward modeling

Training a model to judge responses

- PRM
- Reward

⚡ ⇒ LLM support

Offline methods

(data-driven) Model learns from human preference datasets or supervised signals

- SFT
- DPO
- ORPO
- BCO
- CPO
- KTO

Knowledge distillation

Transferring knowledge from a stronger model to a smaller one

- GKD

Supervised Fine-Tuning

SFT is the simplest and most commonly used method for adapting an LLM to a target dataset

- Goal: minimize negative log-likelihood of a sequence
- Simple, stable, and super effective

Supervised Fine-Tuning

SFTTrainer supports both standard and conversational dataset formats

```
# Standard
language_modeling_example = {"text": "The sky is blue."}

# Conversational
messages = [
    {"role": "user", "content": "Hello, how are you?"},
    {"role": "assistant", "content": "I'm doing great. How can I help you today?"},
    {"role": "user", "content": "I'd like to show off how chat templating works!"},
]
```

SFT is easy to instantiate and train

Only needs a model (even just the name!) and a dataset from the Hub to train

```
from trl import SFTTrainer
from datasets import load_dataset

trainer = SFTTrainer(
    model="Qwen/Qwen3-0.6B",
    train_dataset=load_dataset("trl-lib/Capybara", split="train"),
)
trainer.train()
```

SFTTrainer and SFTConfig

```
from trl import SFTTrainer, SFTConfig
from datasets import load_dataset

trainer = SFTTrainer(
    model="Qwen/Qwen3-0.6B",
    train_dataset=load_dataset("trl-lib/Capybara", split="train"),
    args = SFTConfig(
        # Training schedule / optimization
        per_device_train_batch_size = 2,      # Batch size per GPU
        gradient_accumulation_steps = 8,      # Gradients are accumulated over multiple steps → effective batch size = 2 * 8 = 16
        num_train_epochs = 1,                # Number of full dataset passes
        learning_rate = 2e-4,                # Learning rate for the optimizer
        optim = "paged_adamw_8bit",          # Optimizer

        # Logging / reporting
        logging_steps=1,                     # Log training metrics every N steps
        report_to="trackio",                 # Experiment tracking tool

        # Hub integration
        push_to_hub=True,                    # Automatically push the trained model to the Hugging Face Hub
        ...
    )
    peft_config=LoraConfig(),
    # ...
)
trainer.train()
```

Group Relative Policy Optimization

GRPO was described in [DeepSeekMath](#) paper

Variant of Proximal Policy Optimization (PPO), that enhances maths reasoning capabilities while optimizing memory usage.

- Online method
- Optimized behavior using reward functions

Successor of PPO: more stable and memory efficient

GRPO

Steps: generating completions, computing advantage, computing the loss

GRPOTrainer and GRPOConfig

```
from trl import GRPOTrainer, GRPOConfig
import re

def format_reward_func(completions, **kwargs):
    """Reward function that checks if the completion has a specific format."""
    pattern = r"^<think>.*?</think><answer>.*?</answer>$"
    completion_contents = [completion[0]["content"] for completion in completions]
    matches = [re.match(pattern, content) for content in completion_contents]
    return [1.0 if match else 0.0 for match in matches]

trainer = GRPOTrainer(
    model="Qwen/Qwen2-0.5B-Instruct",
    reward_funcs=[format_reward_func, ... ],
    args=GRPOConfig( ... ),
    train_dataset=load_dataset("trl-lib/tldr", split="train"),
    # ...
)
trainer.train()
```

GRPOConfig detail

```
from trl import GRPOConfig

# Configure training arguments using GRPOConfig
training_args = GRPOConfig(
    # ... Similar to SFTConfig

    # Parameters that control de data preprocessing
    max_completion_length=512, # default: 256
    num_generations=8, # default: 8
    max_prompt_length=512, # default: 512

)
```

OpenR1

Initiative by HF to replicate and extend the techniques behind DeepSeek-R1 🐳

This model was built using SFT+GRPO!

Can we improve online training?

Some trainers work online → the model generates completions during training to compute the reward signal to compute the reward signal

Can we improve online training?

Bottleneck! Generation is slow and inefficient

vLLM solves this problem and is supported by TRL

You can call it from the **CLI**

```
CUDA_VISIBLE_DEVICES=0,1,2,3 trl vllm-serve --model Qwen/Qwen2.5-7B --tensor-parallel-size 2 --data-parallel-size 2
```

```
from trl import GRPOConfig

training_args = GRPOConfig(
    ...,
    use_vllm=True,
    vllm_mode="server", # default value, can be omitted. Can also be "colocate"
)
```

But can we scale training?

TRL also integrates seamlessly with accelerate and DeepSpeed (model sharding, zero redundancy optimized, mixed precision training, offloading...)  deepspeed

But can we scale training?

In the config we specify num of machines, num of processes...

```
accelerate launch --config_file examples/accelerate_configs/deepspeed_zero2.yaml train.py
```

But can we scale training?

Train long context via **context parallelism** (accelerate): by splitting the sequence across multiple GPUs

Even **ND-parallelism** (N model replicas, N devices, tensor parallelism, context parallelism)

```
accelerate launch --config_file context_parallel_2gpu.yaml train.py
```

```
from trl import SFTConfig

training_args = SFTConfig(
    # required
    pad_to_multiple_of=4,          # ensures divisibility by cp_size * 2
    # to get the most out of CP
    max_length=400000,            # long sequence length
    packing=True,                 # use packing to reduce padding
    use liger_kernel=True,        # compatible with CP
    gradient_checkpointing=False, # The activation_checkpointing in FSDP config and
    # the gradient_checkpointing in training arg can't be set to True simultaneously
    per_device_train_batch_size=1,
    ...
)
```

But can we scale training?

Context Parallelism (CP) with *Qwen/Qwen3-8B* scales to over 300k tokens in 8GPUs 🙌

But can we scale training?

nanotron / ultrascale-playbook

The Ultra-Scale Playbook: Training LLMs on GPU Clusters

We ran over 4,000 scaling experiments on up to 512 GPUs and measured throughput (size of markers) and GPU utilization (color of markers). Note that both are normalized per model size in this visualization.

The Ultra-Scale
Playbook: Training LLMs
on GPU Clusters

Optimizing all the things!

Transformers already provides us with some optimizing strategies like gradient checkpointing and we also have LoRA/QLora. In addition, TRL has:

- Truncation
- Packing
- Padding-free
- Padding sequences to a multiple
- Liger kernels 
- Activation offloading

We developed optimized notebooks for training in [free Colab](#).

For even more optimized training, we also have Unsloth 

Optimizing is easy

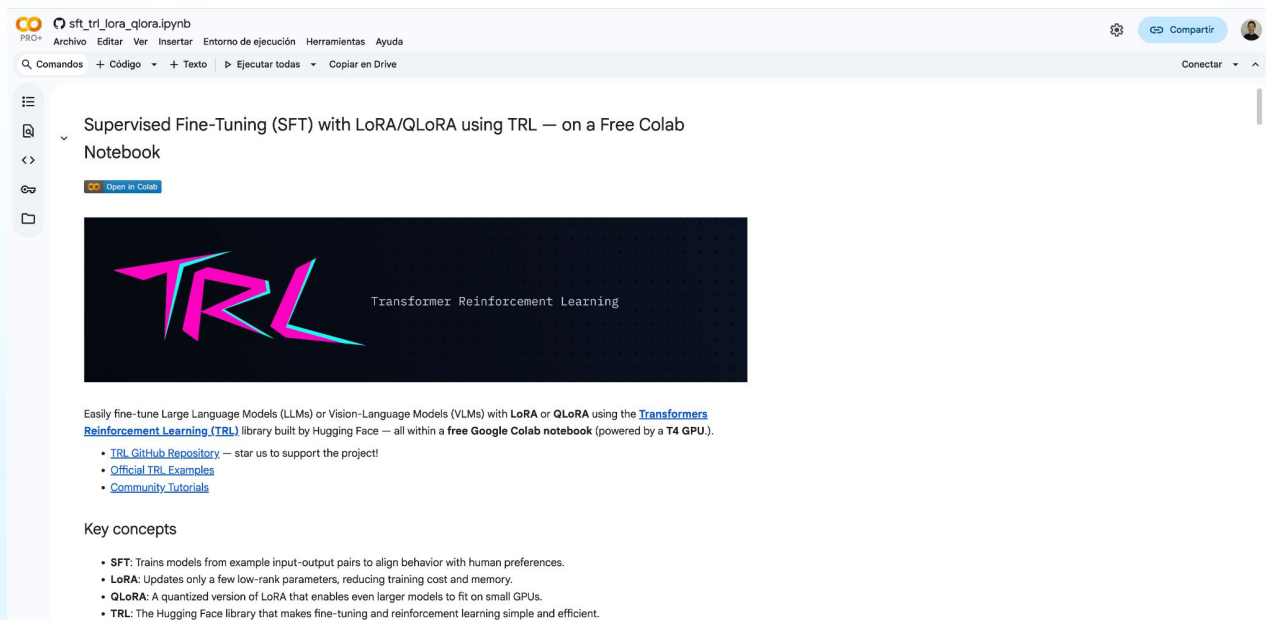

```
from trl import SFTConfig

training_args = SFTConfig(
    max_length=1024,                # (Truncation) Maximum input sequence length
    packing=True                    # Packing
    padding_free=True, model_init_kwargs={"attn_implementation": "flash_attention_2"}, # Padding-free
    pad_to_multiple_of=2048         # Padding sequences to a multiple
    use_liger_kernel=True,          # Enable Liger kernel optimizations for faster training
    activation_offloading=True,      # Offload activations to CPU to reduce GPU memory usage

    gradient_checkpointing=True,     # Save memory by re-computing activations during backpropagation
)
```

Optimizing for GPU poors

We developed [notebooks](#) for training (14B) models in free Colab!

The screenshot shows a Google Colab notebook interface. The title bar indicates the notebook is named 'sft_trl_lora_qlora.ipynb'. The main content area features a large graphic with the text 'TRL Transformer Reinforcement Learning' in a stylized, colorful font. Below the graphic, there is a paragraph of text explaining that the notebook is for easily fine-tuning Large Language Models (LLMs) or Vision-Language Models (VLMs) with LoRA or QLoRA using the Transformers Reinforcement Learning (TRL) library. It also includes links to the TRL GitHub Repository, Official TRL Examples, and Community Tutorials. At the bottom, there is a section titled 'Key concepts' with a bulleted list of points.

Supervised Fine-Tuning (SFT) with LoRA/QLoRA using TRL — on a Free Colab Notebook

Open in Colab

TRL Transformer Reinforcement Learning

Easily fine-tune Large Language Models (LLMs) or Vision-Language Models (VLMs) with **LoRA** or **QLoRA** using the [Transformers Reinforcement Learning \(TRL\)](#) library built by Hugging Face — all within a **free Google Colab notebook** (powered by a **T4 GPU**).

- [TRL GitHub Repository](#) — star us to support the project!
- [Official TRL Examples](#)
- [Community Tutorials](#)

Key concepts

- **SFT:** Trains models from example input-output pairs to align behavior with human preferences.
- **LoRA:** Updates only a few low-rank parameters, reducing training cost and memory.
- **QLoRA:** A quantized version of LoRA that enables even larger models to fit on small GPUs.
- **TRL:** The Hugging Face library that makes fine-tuning and reinforcement learning simple and efficient.

HF jobs + TRL

Models can be trained using HF's infra via HF jobs

- **trl-jobs** cli package
- **hf jobs** (cli or python)

```
# pip install trl-jobs
trl-jobs sft --model_name Qwen/Qwen3-0.6B --dataset_name trl-lib/Capybara
```

```
hf jobs uv run \
  --flavor a100-large \
  --with trl \
  --secrets HF_TOKEN \
  train.py
```

```
from huggingface_hub import run_uv_job

run_uv_job(
    "train.py",
    dependencies=["trl"],
    flavor="a100-large",
    secrets={"HF_TOKEN": "hf_..."},
)
```

Multimodality

TRL supports VLMs in many trainers, including [examples](#) and recipes.

- SFT
- DPO (Direct Preference Optimization)
- MPO (Mixed Preference Optimization)
- GRPO (Group Relative Policy Optimization)
- GSPO (Group Sequence Policy Optimization)
- RLOO (Reinforce Leave One Out)
- Online DPO

Multimodality

Native SFT support for VLMs

You can still use your own collator

```
from trl import SFTConfig, SFTTrainer
from datasets import load_dataset

trainer = SFTTrainer(
    model="Qwen/Qwen2.5-VL-3B-Instruct",
    args=SFTConfig(max_length=None), # To avoid truncation that may remove image tokens during training
    train_dataset=load_dataset("trl-lib/llava-instruct-mix", split="train"),
)
trainer.train()
```

[Example dataset](#)

Post training a VLM for reasoning with GRPO using TRL

Authored by: [Sereno Padoa](#)

WARNING: This notebook is resource-intensive and requires substantial computational power. If you're running this in Colab, it will utilize an A100 GPU.

In this recipe, we'll demonstrate how to post-train a **Vision Language Model (VLM)** using **GRPO** for adding reasoning capabilities to a VLM using the Hugging Face ecosystem, specifically with the **Transformer Reinforcement Learning (TRL)** library.

We'll be fine-tuning **Qwen2.5-VL-72B-Instruct** using a subset of the **lmms-lab/multimodal-open-r1-8k-verified** dataset. This dataset includes images with problem descriptions along with their solution and thinking trace to reach that solution. We'll leverage this data format, along with the GRPO reward functions, to teach the model how to reason to reach the solution.

Fine-Tuning a Vision Language Model (Qwen2-VL-7B) with the Hugging Face Ecosystem (TRL)

Authored by: [Sereno Padoa](#)

WARNING: This notebook is resource-intensive and requires substantial computational power. If you're running this in Colab, it will utilize an A100 GPU.

In this recipe, we'll demonstrate how to fine-tune a **Vision Language Model (VLM)** using the Hugging Face ecosystem, specifically with the **Transformer Reinforcement Learning (TRL)** library to demonstrate how you can tailor VLMs to suit your specific needs, even when working with consumer-grade GPUs.

Model & Dataset Overview

We'll be fine-tuning the **Qwen2-VL-7B** model on the **ChartQA** dataset. This dataset includes images of various chart types paired with question-answer pairs—ideal for enhancing the model's visual question-answering capabilities.

Additional Resources

If you're interested in more VLM applications, check out:

- Multimodal Retrieval-Augmented Generation (RAG) Recipe:** where I guide you through building a RAG system using Document Retrieval (CoPal) and Vision Language Models (VLMs).
- Phi-Score's tutorial:** an excellent deep dive into fine-tuning multimodal LLMs with TRL.
- Merco Novati's smol-vision repository:** a collection of engaging notebooks on cutting-edge vision and multimodal AI topics.

Fine-Tuning a Vision Language Model with TRL using MPO

Authored by: [Sereno Padoa](#)

In this recipe, we'll demonstrate how to fine-tune a **Vision Language Model (VLM)** using **Mixed Preference Optimization (MPO)** with the **Transformer Reinforcement Learning (TRL)** library.

MPO is a training approach that combines multiple optimization objectives and was introduced in the paper **Enhancing the Reasoning Ability of Multimodal Large Language Models via Mixed Preference Optimization**. It is part of the **Direct Preference Optimization (DPO)** trainer and works by combining multiple loss functions with different weights, enabling more sophisticated optimization strategies.

We'll fine-tune **Qwen2.5-VL-72B-Instruct**, a small VLM with strong performance, using a preference dataset to help the model align with desired outputs. Check out [this blog post](#) to learn more about preference optimization for vision-language models.

The dataset we'll use is **huggingfaceh4/rlaif-v_formatted**, a specially formatted version of the **RLAIF-V-Dataset**. This dataset contains pairs of prompt + image, along with a chosen and rejected response for each sample. The final goal of the fine-tuning process is to train a model that consistently prefers the chosen answers over the rejected ones, thereby reducing hallucinations. To achieve this, multiple loss functions will be used in combination.

Fine-Tuning SmoIVLM using direct preference optimization (DPO) with TRL on a consumer GPU

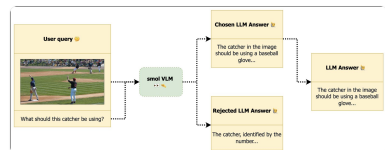

Authored by: [Sereno Padoa](#)

In this recipe, we'll guide you through fine-tuning a **smol VLM** using **Direct Preference Optimization (DPO)** using the **Transformer Reinforcement Learning (TRL)** library to demonstrate how you can tailor VLMs to suit your specific needs, even when working with consumer-grade GPUs.

We'll fine-tune **SmolVLM** using a **preference dataset** to help the model align with desired outputs. SmolVLM is a highly-performant and memory-efficient model, making it an ideal choice for this task. If you're new to **Preference Optimization** for language or vision-language models, check out [this blog](#) for an in-depth introduction.

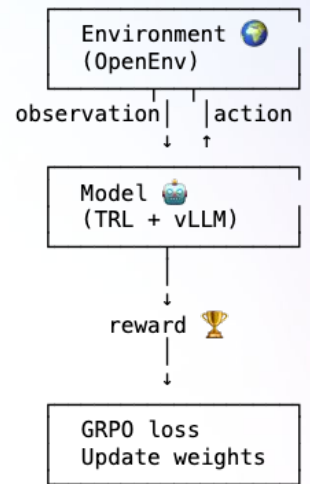

The dataset we'll use is **huggingfaceh4/rlaif-v_formatted**, which contains pairs of prompt + image along with a chosen and rejected answer for each pair. The goal of this fine-tuning process is to make the model consistently prefer the **chosen answers** from the dataset, reducing hallucinations.

This notebook has been tested using an **NVIDIA 4 GPU**.

OpenEnv for training agents

- So far: models learn from static datasets or simple reward functions
- Next step: **Models that learn by interacting with environments**
- Problem: every environment has its own API, format, logic → no standard
- [OpenEnv](#) → **unifies and integrates** with TRL (although TRL supports *any* framework)

OpenEnv for training agents

Framework for creating environments that can be used for training

- **Standardized:** Simple interface → `reset()` + public methods as tools
- **Shearable:** Public & discover envs of the Hub
- **Flexible:** Run locally, in Docker or on HF Spaces
- **Integrated:** Native integration with TRL's *GRPOTrainer*
- Some examples: browser, CARLA simulator, coding sandbox, games...

Example: learning to drive with CARLA

- [CARLA](#): autonomous driving simulator
- Scenario: vehicle heading towards pedestrians
- Model must observe, reason, and act to minimize harm
- Tools:
 - *observe()*: look at the scene
 - *emergency_stop()*: maximum braking
 - *lane_change(direction)*: swerve left/right
- Synchronous simulation
- Runs on HF Spaces, scalable with multiple instances

```

class CarlaEnv:

    def __init__(self):
        self.client = CarlaEnv(base_url="https://sergiopaniego-carla-env.hf.space")

    def reset(self, **kwargs) → str:
        result = self.client.reset(scenario_name="trolley_micro_escape_exists")
        self.reward = 0.0
        return describe(result.observation)

    def observe(self) → str:
        """Get the current scene description."""
        result = self._advance()
        self.reward = result.observation.rubric_reward or 0.0
        return describe(result.observation)

    def emergency_stop(self) → str:
        """Apply maximum braking to stop the vehicle."""
        self.client.step(CarlaAction(action_type="emergency_stop"))
        result = self._advance()
        self.reward = result.observation.rubric_reward or 0.0
        return describe(result.observation)

    def lane_change(self, direction: str) → str:
        """Change lane to avoid obstacles. Direction: 'left' or 'right'."""
        self.client.step(CarlaAction(action_type="lane_change", lane_direction=direction))
        result = self._advance()
        self.reward = result.observation.rubric_reward or 0.0
        return describe(result.observation)

    def reward_func(completions, environments, **kwargs):
        return [env.reward for env in environments]

trainer = GRPOTrainer(
    model="Qwen/Qwen3-0.6B",
    reward_funcs=reward_func,
    environment_factory=CarlaEnv, # 3 tools auto-registered!
)
trainer.train()

```

CARLA: from crashing to avoiding

Qwen3-0.6B with GRPO

- Step 1 –  `observe()`
 - Speed: 39.6 km/h | 3 pedestrians at ~19m ahead
- Step 2 –  `emergency_stop()` # start braking to reduce speed
 - Speed: 27.4 km/h | pedestrians at ~14m
- Step 3 –  `lane_change("left")` # swerve while still slowing down
 - Speed: 27.6 km/h | pedestrians at ~10m (moving to adjacent lane)
- Step 4 –  `emergency_stop()` # full stop to ensure no collision
 - Speed: 0.0 km/h | pedestrians at ~6m (car stopped, collision avoided ✓)
